

MaceStyle: No-AI Production

The Mace-side steps to stand up the Function and let me deploy it

MaceStyle can go to production **this sprint**, running entirely inside Mace's Azure and Microsoft 365. In this mode the AI rules are switched **off**, so no document text leaves Mace — **no external data, no governance wait**. It enforces the deterministic core of the Style Guide (British spelling, contractions, symbols, numbers, fonts, colours). AI-powered judgement rules layer on later with zero rework — same codebase, one setting. This sheet covers the three things **Mace needs to do** so I can deploy and finish the wiring.

PREREQUISITES

- A **Mace Azure subscription + resource group** (UK South) to own the service.
- Someone with **Owner/Contributor on that resource group** to run Steps 2–3, and **access to the app registration** (Step 1).
- No AI resource, no Marketplace step, no US data zone — this mode needs none of it.

Step 1 — Reuse the existing app registration MACE

MaceStyle authenticates to SharePoint with an app registration that **already exists on the Mace tenant** and already has the right permission granted. Do not create a new one — just confirm and supply a secret:

App registration	MaceStyleValidator-App
Tenant ID	f9300280-... (Mace)
Client (application) ID	b1b09e94-...
Permission	Graph Sites.Selected — fullcontrol on the MaceWayControlCentre site (granted by Sapna Gupta)

To do: (a) confirm the `Sites.Selected` grant on MaceWayControlCentre is still in place; (b) provide a **valid client secret** — the current one expires 31 May 2028, or generate a fresh one. **Send the secret to me via a secure channel** (or, preferred, drop it straight into the Function App settings / Key Vault in Step 2 so I never handle the raw value).

Step 2 — Create the Function App MACE

Create an Azure Function App in the Mace resource group with these settings:

Type	Function App — Flex Consumption plan
Runtime	Python 3.11 , Linux
Region	UK South
Name	e.g. <code>func-macestyle-prod</code> (Mace convention)

A storage account is created automatically. Nothing else is needed at creation time — I set the app configuration as part of the deploy.

Step 3 — Give me deploy access MACE

Grant my Mace account (`stephen.cummins@macegroup.com`) an RBAC role on the Function App (or the resource group) so I can deploy the code and set its configuration from VS Code:

Role	Contributor on the Function App (or <i>Website Contributor</i> if you prefer least-privilege)
Scope	The Function App from Step 2 (or its resource group)
Assignee	<code>stephen.cummins@macegroup.com</code>

HAND ME THESE THREE THINGS

- Subscription ID + resource group name + the Function App name/region (Step 2)
- Confirmation my account has the deploy role (Step 3)
- The app-registration client secret — securely, or pre-loaded into app settings (Step 1)

What I do next ME

Once the above is in place, no further Mace admin effort is needed. I will:

1. **Deploy the code** to the Function App from VS Code.
2. **Set the app settings** — the SharePoint credentials + list IDs, plus `ENABLE_CLAUDE_AI=false` (the switch that keeps it AI-free) and the endpoint access key. *No AI variables are set in this mode.*
3. **Re-point the existing Power Automate flow** ("Mace Document Style Validator") at the new Function URL.
4. **Verify** end-to-end on a test document and confirm the deterministic corrections apply.
